#### COMP 3270 FALL 2018

### **Programming Project: Autocomplete**

Name: Zachary Parker Date Submitted: 11-26-18

1. **Pseudocode**: Understand the strategy provided for *TrieAutoComplete*. State the algorithm for the functions <u>precisely using numbered steps that follow the pseudocode conventions</u> that we use. Provide an approximate efficiency analysis by filling the table given below, for your algorithm.

#### Add

Pseudocode:

```
Add(word: string, weight: double)
      if word is null
             throw an exception
       if weight < 0
             throw an exception
5
6
7
       Node curr = root of tree
       Node nextNode = null
      char index = '-'
8
      for i to word.length
             index = the character in word at index i
10
             nextNode = the child of curr with character index
11
             if nextNode is null
12
                    instantiate nextNode with character index,
                    parent curr, and given weight
13
                    add new node to children map
14
             if curr's subtree max weight < weight
                    curr's subtree max weight = weight
15
16
             point curr to nextNode
17
       set curr's word value
       set curr's weight
19
       set that curr is a word
20
```

# • Complexity analysis:

| Step #          | Complexity stated as O(_) |
|-----------------|---------------------------|
| 1               | O(1)                      |
| 2               | O(1)                      |
| <mark>3</mark>  | O(1)                      |
| <mark>4</mark>  | O(1)                      |

| <mark>11</mark> | O(n)                      |
| <mark>12</mark> | O(n)                      |
| <mark>13</mark> | O(n)                      |
| <mark>14</mark> | O(n)                      |
| <mark>15</mark> | O(n)                      |
| <mark>16</mark> | O(n)                      |
| <mark>17</mark> | O(1)                      |
| <mark>18</mark> | O(1)                      |
| <mark>19</mark> | O(1)                      |

Complexity of the algorithm = O(n)

### topMatch

### Pseudocode:

```
topMatch(prefix: string)
      if prefix is null
             throw an exception
      nodeQueue = new priority queue of Nodes using a
3
      reverse weight comparator
       Node curr = root of tree
5
       char index = '-'
6
       boolean wordExists = true
7
      string empty = ""
8
      String topMatch = ""
      for i to prefix.length
10
             index = the character in the word at index i
11
             if a child of curr contains the value of index
12
                    point curr to that child
<mark>13</mark>
             else
14
                    wordExists = false
15
                    break
      if (wordExists is false)
16
17
             return empty
      while (curr is a word and curr's weight < curr's
18
       subtree max weight)
19
             for every node in curr's children
20
                    add that node to nodeQueue
             point curr to the head of queue and remove
21
              element from queue
22
       topMatch = curr's word value
      return topMatch
23
```

| <mark>29</mark> | O(1)                      |

Complexity of the algorithm =  $O(n^2)$ 

2.**Testing**: Complete your test cases to test the *TrieAutoComplete* functions based upon the criteria mentioned below.

### **Test of correctness:**

Assuming the trie already contains the terms {"ape, 6", "app, 4", "ban, 2", "bat, 3", "bee, 5", "car, 7", "cat, 1"}, you would expect results based on the following table:

| Query | k   | Result                                     |
|-------|-----|--|
| ""    | -   | Car  |
| "a"   | -   | Ape  |
| "ap"  | -   | Ape  |
| "b"   | -   | Bee  |
| "ba"  | -   | Bat  |
| "c"   | -   | Car  |
| "ca"  | -   | Car  |
| "cat" | -   | Cat  |
| "d"   | -   | "  |
| ""    | -   | ,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,     |
| ""    | 8   | {"car", "ape", "bee", "app", "bat", "ban", |
| ,,,,  |     | "cat"}                                     |
|       | 1   | {"car"}                                    |
| ""    | 2   | {"car", "ape"}                             |
| ""    | 3   | {"car", "ape", "bee"}                      |
| "a"   | 1   | {"ape"}                                    |
| "ap"  | 1   | {"ape"}                                    |
| "b"   | 2   | {"bee", "bat"}                             |
| "ba"  | 2   | {"bee", "bat"}                             |
| "d"   | 100 | {}   |

Test cases have been provided in the file AutocompleteTest.java.

3. **Analysis**: Answer the following questions. Use data wherever possible to justify your answers, and keep explanations brief but accurate:

NOTE: Whenever fourletterwords.txt and fourletterwordshalf.txt are compared in any of the following graphs, note that the letter "a" in fourletterwordshalf is considered synonymous to the letter "n" in fourletterwords.

i. What is the order of growth (big-Oh) of the number of compares (in the worst case) that each of the operations in the *Autocompletor* data type make?

add: O(n)

topMatch: O(n²)

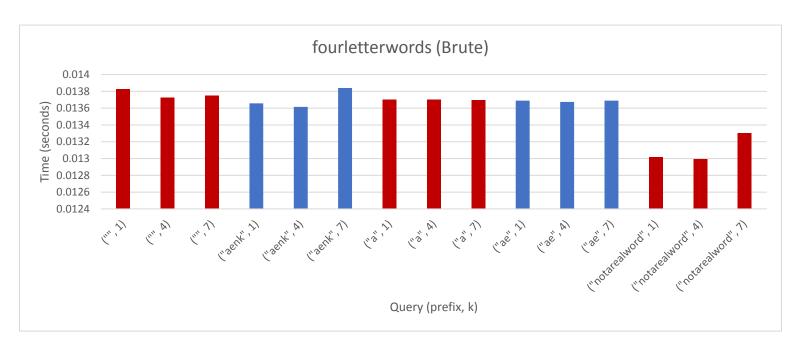

topMatches: O(n<sup>2</sup>)

This information is presented above in Problem 1.

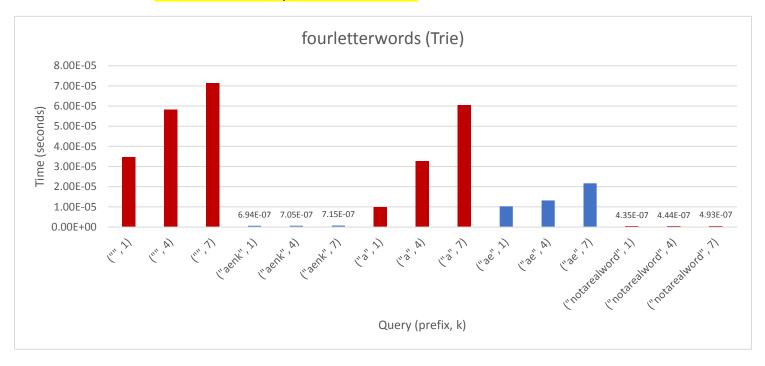

ii. How does the runtime of *topMatches()* vary with k, assuming a fixed prefix and set of terms? Provide answers for *BruteAutocomplete* and *TrieAutocomplete*. Justify your answer, with both data and algorithmic analysis.

The following observations were made using the given AutocompletorBenchmark class and fourletterwords text file.

BruteAutocomplete: The runtime of topMatches() is nearly the exact same for a fixed prefix and set of terms. This suggests that the runtime of topMatches() in this given implementation is not actually affected the value of k.

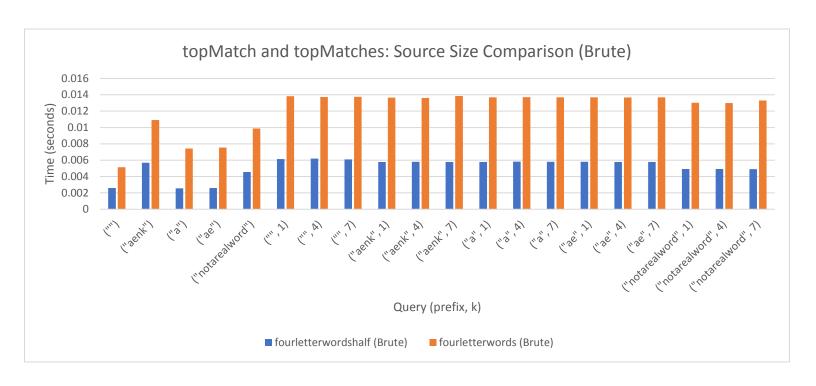

TrieAutocomplete: The runtime of topMatches() consistently increases as the value of k increases. This suggests that increasing values of k are correlated to a slower runtime. This may at least partly be attributed to the fact that TrieAutocomplete has the opportunity to break out of its loop, but BruteAutocomplete cannot do so.

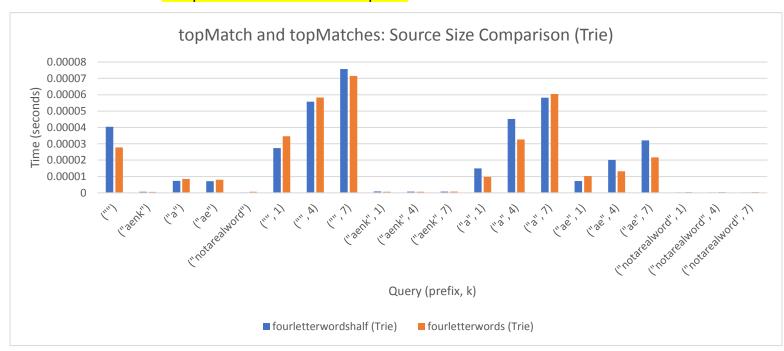

iii. How does increasing the size of the source and increasing the size of the prefix argument affect the runtime of *topMatch* and *topMatches*? (Tip: Benchmark each implementation using fourletterwords.txt, which has all four-letter combinations from aaaa to zzzz, and fourletterwordshalf.txt, which has all four-letter word combinations from aaaa to mzzz. These datasets provide a very clean distribution of words and an exact 1-to-2 ratio of words in source files.)

For BruteAutocomplete, increasing the size increases the runtime of topMatch and topMatches in a linear fashion. This is to say that doubling the input will, on average, double the runtime of these functions.

For TrieAutocomplete, increasing the size of the source does not discernibly alter the runtime of topMatch and topMatches. This means that this implementation is far more scalable in comparison to BruteAutocomplete.

- 4. Graphical Analysis: Provide a graphical analysis by comparing the following:
  - i. The big-Oh for *TrieAutoComplete* after analyzing the pseudocode and big-Oh for *TrieAutoComplete* after the implementation.

### Pseudocode:

add: O(n)

topMatch: O(n<sup>2</sup>)

topMatches: O(n<sup>2</sup>)

**Implementation**:

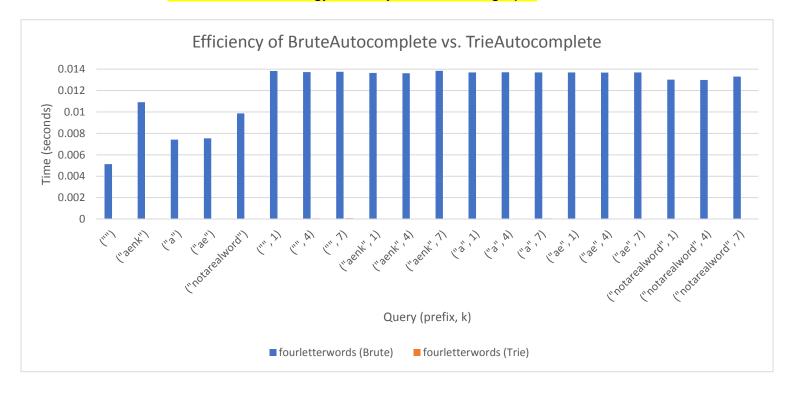

add: O(n)

topMatch: O(n<sup>2</sup>)

topMatches: O(n<sup>2</sup>)

ii. Compare the *TrieAutoComplete* with *BruteAutoComplete*.

In all given benchmark cases, TrieAutocomplete is orders of magnitude more efficient than BruteAutocomplete. Note that, when compared to the brute force implementation, the allotted time of the trie strategy is hardly visible in the graph.

The next chart represents the same data but more clearly represents TrieAutocomplete's allotted time when compared to BruteAutocomplete.
